Chapter 1

Introduction

Chapter 2

A systematic literature review of the Prisoner's Dilemma.

The Prisoner's Dilemma is a well known game used since the 1950's as a framework for studying the emergence of cooperation; a topic of continuing interest for mathematical, social, biological and ecological sciences. The iterated version of the game, the Iterated Prisoner's Dilemma, attracted attention in the 1980's after the publication of the "The Evolution of Cooperation" and has been a topic of pioneering research ever since. The aim of this paper is to provide a systematic literature review on Prisoner's Dilemma related research. This is achieved by reviewing selected pieces of work and partition the literature into five different sections with each reviewing a different aspect of research. The questions answered in this manuscript are (1) what are the research trends in the field (2) what are the already existing results within the field.

2.1 Introduction

Based on the Darwinian principle of survival of the fittest cooperative behaviour should not be favoured, however, cooperation is plentiful in nature. A paradigm of understanding the emergence of these behaviours is a particular two player non-cooperative game called the Prisoner's Dilemma (PD), originally described in **Flood1958**.

In the PD each player has two choices, to either be selfless and cooperate or to be selfish and defect. Each decision is made simultaneously and independently. The utility of each player is influenced by its own behaviour, and the behaviour of the opponent. Both players do better if they choose to cooperate than if both choose to defect. However, a player has the temptation to deviate as that player will receive a higher payoff than that of mutual cooperation. Players' payoffs are generally represented by (2.1). Both players receive a reward for mutual cooperation, R, and a payoff P for mutual defection. A player that defects while the other cooperates receives a payoff of T, whereas the

cooperator receives S. The dilemma exists due to constraints (2.2) and (2.3).

$$\begin{pmatrix} R & S \\ T & P \end{pmatrix} \tag{2.1}$$

$$T > R > P > S \tag{2.2}$$

$$2R > T + S \tag{2.3}$$

Another common representation of the payoff matrix is given by (2.4), where b is the benefit of the altruistic behaviour and c it's its cost (constraints (2.2) and (2.3) still hold).

$$\begin{pmatrix} b - c & c \\ b & 0 \end{pmatrix} \tag{2.4}$$

Constraints (2.2-2.3) guarantee that it never benefits a player to cooperate, indeed mutual defection is a Nash equilibrium. However, when the game is studied in a manner where prior outcome matters, defecting is no longer necessarily the dominant choice.

The repeated form of the game is called the Iterated Prisoner's Dilemma (IPD) and theoretical works have shown that cooperation can emerge once players interact repeatedly. Arguably, the most important of these works is Robert Axelrod's "The Evolution of Cooperation" **Axelrod1984**. In his book Axelrod reports on a series of computer tournaments he organised. In these tournaments academics from several fields were invited to design computer strategies to compete. Axelrod's work showed that greedy strategies did very poorly in the long run whereas altruistic strategies did better. "The Evolution of Cooperation" is considered a milestone in the field but it is not the only one. On the contrary, the PD has attracted attention ever since the game's origins.

This manuscript presents a qualitative description of selected pieces of work. These have been separated into five sections, each reviewing a different aspect of research. The topics reviewed at each section are the following:

- section 2.2, **Origins of the Prisoner's Dilemma**.

- section 2.3, **Axelrod's tournaments and intelligent design of strategies**.

- section 2.4, **Evolutionary dynamics**

- section 2.5, **Structured strategies and training**.

- section 2.6, **Software**.

The aim of this work is to provide a concrete summary of the existing literature on the PD. This is done to provide a review which will allow the research community to understand overall trends in the field, and already existing results.

2.2 Origins of the prisoner's dilemma

The origin of the PD goes back to the 1950s in early experiments conducted at RAND **Flood1958** to test the applicability of games described in **VonNeumann1944**. The game received its name later the same year. According to **Tucker1983**, Albert W. Tucker (the PhD supervisor of John Nash **Nash1951**), in an attempt to deliver the game with a story during a talk described the players as prisoners and the game has been known as the Prisoner's Dilemma ever since.

The early research on the IPD was limited. The only source of experimental results was through human subject research where pairs of participants simulated plays of the game. Human subject research had disadvantages. Humans could behave randomly and in several experiments both the size and the background of the individuals were different, thus comparing results of two or more studies became difficult.

The main aim of these early research experiments was to understand how conditions such as the gender of the participants **Evans1966**; **Lutzker1961**; **Mack1971**, the physical distance between the participants **Sensenig1972**, the effect of their opening moves **Tedeschi1968** and even how the experimenter, by varying the tone of their voice and facial expressions **Gallo1968**, could influence the outcomes and subsequently the emergence of cooperation. An early figure that sought out to understand several of these conditions was the mathematical psychologist Anatol Rapoport. The results of his work are summarised in **rapoport1965**.

Rapoport was also interested in conceptualising strategies that could promote international cooperation. Decades later he would submit the winning strategy (Tit for Tat) of the first computer tournament, run by Robert Axelrod. In the next section these tournaments, and several strategies that were designed by researchers, such as Rapoport, are introduced.

2.3 Axelrod's tournaments and intelligently designed strategies

As discussed in Section 2.2, before 1980 a great deal of research was done in the field, however, as described in **Axelrod2012**, the political scientist Robert Axelrod believed that there was no clear answer to the question of how to avoid conflict, or even how

an individual should play the game. Combining his interest in artificial intelligence
and political science Axelrod created a framework for exploring these questions using
computer tournaments. Axelrod asked researchers to design a strategy with the purpose
of wining an IPD tournament. This section covers Axelrod's original tournaments as
well as research that introduced new intelligently designed strategies.

Axelrod's tournaments made the study of cooperation of critical interest. As described
in **Rapoport2015**, "Axelrod's "new approach" has been extremely successful and im-
mensely influential in casting light on the conflict between an individual and the collec-
tive rationality reflected in the choices of a population whose members are unknown and
its size unspecified, thereby opening a new avenue of research". In a collaboration with
a colleague, Douglas Dion, Axelrod in **Axelrod1988** summarized a number of works
that were immediately inspired from the "Evolution of Cooperation", and **Jurisic2012**
gives a review of tournaments that have been conducted since the originals.

The first reported computer tournament took place in 1980 **Axelrod1980a**. A total
of 13 strategies were submitted, written in the programming languages Fortran or
Basic. Each competed in a 200 turn match against all 12 opponents, itself and a
player that played randomly (called **Random**). This type of tournament is referred
to as a round robin. The tournament was repeated 5 times to get a more stable
estimate of the scores for each pair of play. Each participant knew the exact number
of turns and had access to the full history of each match. Furthermore, Axelrod
performed a preliminary tournament and the results were known to the participants.
This preliminary tournament is mentioned in **Axelrod1980a** but no details were given.
The payoff values used for equation (2.1) were $R = 3, P = 1, T = 5$ and $S = 0$. These
values are commonly used in the literature and unless specified will be the values used
in the rest of the works described here.

The winner of the tournament was determined by the total average score and not by
the number of matches won. The strategy that was announced the winner was the
strategy submitted by Rapoport, **Tit For Tat**. The success of Tit for Tat came as a
surprise. It was not only the simplest submitted strategy, it would always cooperates on
the first round and then mimic the opponent's previous move, but it had also won the
tournament even though it could never beat any player it was interacting with.

In order to further test the results Axelrod performed a second tournament in 1980 **Axelrod1980b**.
The second tournament received much more attention and had a total of 62 entries.
The participants knew the results of the previous tournament and the rules were similar
with only a few alterations. The tournament was repeated 5 times and the length of
each match was not known to the participants. Axelrod intended to use a fixed proba-
bility (refereed to as 'shadow of the future' **Axelrod1988**) of the game ending on the
next move. However, 5 different number of turns were selected for each match 63, 77,

151, 308 and 401, such that the average length would be around 200 turns.

Nine of the original participants competed again in the second tournament. Two
strategies that remained the same were Tit For Tat and **Grudger**. Grudger is a strat-
egy that will cooperate as long as the opponent does not defect, submitted by James
W. Friedman. The name Grudger was give to the strategy in **Li2014**, though the
strategy goes by many names in the literature such as, Spite **Beaufils1997**, Grim
Trigger **Banks1990** and Grim **Van2015**. New entries in the second tournament
included **Tit for Two Tats** submitted by John Maynard Smith and **KPavlovC**.
KPavlovC, is also known as Simpleton **rapoport1965**, introduced by Rapoport or just
Pavlov **Nowak1993**. The strategy is based on the fundamental behavioural mecha-
nism win-stay, lose-shift. Pavlov is heavily studied in the literature and similarly to
Tit for Tat it is used in tournaments today and has had many variants trying to build
upon it's success, for example **PavlovD** and **Adaptive Pavlov Li2007**.

Despite the larger size of the second tournament none of the new entries managed to
outperform the simpler designed strategy. The winner was once again Tit for Tat.
Axelrod deduced the following guidelines for a strategy to perform well:

- The strategy would start of by cooperating.

- It would forgive it's opponent after a defection.

- It would always be provoked by a defection no matter the history.

- It was simple.

The success of Tit for Tat, however, was not unquestionable. Several papers showed
that stochastic uncertainties severely undercut the effectiveness of reciprocating strate-
gies and such stochastic uncertainties have to be expected in real life situations **Milinski1987**.
For example, in **Molander1985** it is proven that in an environment where **noise** (a
probability that a player's move will be flipped) is introduced two strategies playing
Tit for Tat receive the same average payoff as two Random players. Hammerstein,
pointed out that if by mistake, one of two Tit for Tat players makes a wrong move,
this locks the two opponents into a hopeless sequence of alternating defections and
cooperations **Hammerstein1984**.

The poor performance of the strategy in noisy environments was also demonstrated in
tournaments. In **Bendor1991**; **Donninger1986** round robin tournaments with noise
were performed, and Tit For Tat did not win. The authors concluded that to overcome
the noise more generous strategies than Tit For Tat were needed. They introduced the
strategies **Nice and Forgiving** and **OmegaTFT** respectively.

A second type of stochastic uncertainty is misperception, where a player's action is
made correctly but it is recorded incorrectly by the opponent. In **Wu1995**, a strategy

called **Contrite Tit for Tat** was introduced that was more successful than Tit for Tat in such environments. The difference between the strategies was that Contrite Tit for Tat was not so fast to retaliate against a defection.

Several works extended the reciprocity based approach which has led to new strategies. For example Gradual **Beaufils1997** which was constructed to have the same qualities as those of Tit for Tat except one, **Gradual** had a memory of the game since the beginning of it. Gradual recorded the number of defections by the opponent and punished them with a growing number of defections. It would then enter a calming state in which it would cooperates for two rounds. In a tournament of 12 strategies, including both Tit for Tat and Pavlov, Gradual managed to outperformed them all. A strategy with the same intuition as Gradual is **Adaptive Tit for Tat tzafestas-2000a**. Adaptive Tit for Tat does not keep a permanent count of past defections, it maintains a continually updated estimate of the opponent's behaviour, and uses this estimate to condition its future actions. In the exact same tournament as in **Beaufils1997** with now 13 strategies Adaptive Tit for Tat ranked first.

Another extension of strategies was that of teams of strategies **J.P.Delahaye1993Lp**; **J.P.Delahaye1995LIeP**; **A.Rogers2007Ctpw** that collude to increase one member's score. In 2004 Graham Kendall led the Anniversary Iterated Prisoner's Dilemma Tournament with a total of 223 entries. In this tournament participants were allowed to submit multiple strategies. A team from the University of Southampton submitted a total of 60 strategies **A.Rogers2007Ctpw**. All these were strategies that had been programmed with a recognition mechanism by default. Once the strategies recognised one another, one would act as leader and the other as a follower. The follower plays as a **Cooperator**, cooperates unconditionally and the leader would play as a **Defector** gaining the highest achievable score. The followers would defect unconditionally against other strategies to lower their score and help the leader. The result was that Southampton had the top three performers. Nick Jennings, who was part of the team, said that "We developed ways of looking at the Prisoner's Dilemma in a more realistic environment and we devised a way for computer agents to recognise and collude with one another despite the noise. Our solution beats the standard Tit For Tat strategy" **southampton˙blog**.

2.3.1 Memory one Strategies

A set of strategies that have received a lot of attention in the literature are **memory one** strategies. In **nowak1989**, Nowak and Sigmund proposed a structure for studying simple strategies that remembered only the previous turn, and moreover, only recorded the move of the opponent. These are called **reactive** strategies and they can be represented by using three parameters (y, p_1, p_2), where y is the probability to cooperate

in the first move, and p_1 and p_2 the conditional probabilities to cooperate, given that the opponent's last move was a cooperation or a defection. For example Tit For Tat is a reactive strategy and it can be written as $(1, 1, 0)$. Another reactive strategy well known in the literature is **Generous Tit for Tat Nowak1992**.

In **Nowak1990**, Nowak and Sigmund extended their work to include strategies which consider the entire history of the previous turn to make a decision. These are called **memory one** strategies. If only a single turn of the game is taken into account and depending on the simultaneous moves of the two players there are only four possible states that the players could be in. These are:

- Both players cooperated, denoted as CC.

- First player cooperated while the second one defected, denoted as CD.

- First player defected while the second one cooperated, denoted as DC.

- Both players defected, denoted as DD.

Thus a memory one strategy can be denoted by the probabilities of cooperating after each state and the probability of cooperating in the first round, (y, p_1, p_2, p_3, p_4). For example Pavlov's memory one representation is $(1, 1, 0, 0, 1)$.

Memory one strategies made an impact when a specific set of memory one strategies were introduced called **Zero-determinant** (ZD) **Press2012**. The American Mathematical Society's news section **hilbe2015** stated that "the world of game theory is currently on fire" and in **Stewart2012** it was stated that "Press and Dyson have fundamentally changed the viewpoint on the Prisoner's Dilemma". ZD are a set of extortionate strategies that can force a linear relationship between the long-run scores of both themselves and the opponent, therefore ensuring that the opponent will never do better than them.

Press and Dyson's suggested ZD strategies were the dominant family of strategies in the IPD. Moreover, they argued that memory is not beneficial. In **Adami2013**; **Knight2017**; **Hilbe2013**; **Hilbe2013b**; **hilbe2015**; **KnightHGC17**; **Knight2019**; **Lee2015**; **Stewart2012** the effectiveness of ZD strategies is questioned. In **Adami2013**, it was shown that ZD strategies are not evolutionary stable, and in **Stewart2012** a more generous set of ZDs, the **Generous ZD**, were shown to outperform the more extortionate ZDs. Finally, in **Knight2017**; **KnightHGC17**; **Knight2019**; **Lee2015**, the 'memory does not benefit a strategy' statement was questioned. A set of more complex strategies, strategies that take in account the entire history set of the game, were trained and proven to be more stable than ZD strategies.

This section covered the original computer tournaments of Axelrod and the early success of Tit For Tat in these tournaments. Though Tit For Tat was considered to be the

most robust basic strategy, reciprocity was found to not be enough in environments with uncertainties. There are at least two properties, that have been discussed in this section, for coping with such uncertainties; generosity and contrition. Generosity is letting a percentage of defections go unpunished, and contrition is lowering a strategy's readiness to defect following an opponent's defection.

In the later part of this section a series of new strategies which were built on the basic reciprocal approaches were presented, followed by the infamous memory one strategies, the zero-determinant strategies. Though the ZDs can be proven to be robust in pairwise interactions they were found to be lacking in evolutionary settings and in computer tournaments. Evolutionary settings and the emergence of cooperation under natural selection are covered in the next section.

2.4 Evolutionary dynamics

As yet, the emergence of cooperation has been discussed in the contexts of the one shot PD game and the IPD round robin tournaments. In the PD it is proven that cooperation will not emerge, furthermore, in a series of influential works Axelrod demonstrated that reciprocal behaviour favours cooperation when individuals interact repeatedly. But does natural selection favours cooperation? Understanding the conditions under which natural selection can favour cooperative behaviour is important in understanding social behaviour amongst intelligent agents **Boyd1987**.

Imagine a mixed population of cooperators and defectors where every time two individuals meet they play a game of PD. In such population the average payoff for defectors is always higher than cooperators. Under natural selection the frequency of defectors will steadily increase until cooperators become extinct. Thus natural selection favours defection in the PD (Figure 2.1). However, there are several mechanisms that allow the emergence of cooperation in an evolutionary context which will be covered in this section.
Figure 2.1: Natural selection favours defection in a mixed population of Cooperators and Defectors.

In the later sections of **Axelrod1980b**, Axelrod discusses an ecological tournament that he performed using the 62 strategies of the second tournament to understand the reproductive success of Tit for Tat. In his ecological tournament the prevalence of each type of strategy in each round was determined by that strategy's success in the previous

round. The competition in each round would become stronger as weaker performers were reduced and eliminated. The ecological simulation concluded with a handful of nice strategies dominating the population whilst exploitative strategies had died off as weaker strategies were becoming extinct. This new result led Axelrod to study the IPD in an evolutionary context based on several of the approaches established by the biologist John M. Smith **Smith1974**; **Smith1979**; **Smith1973**. John M. Smith was a fundamental figure in evolutionary game theory and a participant of Axelrod's second tournament. Axelrod and the biologist William Donald Hamilton wrote about the biological applications of the evolutionary dynamics of the IPD **Axelrod1984** and won the Newcomb-Cleveland prize of the American Association for the Advancement of Science.

In Axelrod's model **axelrod1981** pairs of individuals from a population played the IPD. The number of interactions between the pairs were not fixed, but there was a probability defined as the importance of the future of the game w, where $0 < w < 1$, that the pair would interact again. In **axelrod1981** it was shown that for a sufficient high w Tit For Tat strategies would become common and remain common because they were "collectively stable". Axelrod argued that collective stability implied evolutionary stability (ESS) and that when a collectively stable strategy is common in a population and individuals are paired randomly, no other rare strategy can invade. However, Boyd and Lorderbaum in **Boyd1987** proved that if w, the importance of the future of the game, is large enough then no pure strategy is ESS because it can always be invaded by any pair of other strategies. This was also independently proven in **Pudaite1987**.

All these conclusions were made in populations where the individuals could all interact with each other. In 1992, Nowak and May, considered a structured population where an individual's interactions were limited to its neighbours. More specifically, in **Nowak1992b** they explored how local interaction alone can facilitate population wide cooperation in a one shot PD game. The two deterministic strategies Defector and Cooperator, were placed onto a two dimensional square array where the individuals could interact only with the immediate neighbours. The number of immediate neighbours could be either, fourth, six or eight, as shown in Figure 2.2, where each node represents a player and the edges denote whether two players will interact. This topology is refereed to as spatial topology. Each cell of the lattice is occupied by a Cooperator or a Defector and at each generation step each cell owner interacts with its immediate neighbours. The score of each player is calculated as the sum of all the scores the player achieved at each generation. At the start of the next generation, each lattice cell is occupied by the player with the highest score among the previous owner and their immediate neighbours.

Local interactions proved that as long as small clusters of cooperators form, where they can benefit from interactions with other cooperators while avoiding interactions with defectors, global cooperation will continue. Thus, local interactions proved that even for the PD cooperation can emerge. Moreover in **Ohtsuki2006**, whilst using the payoff matrix (2.4), it was shown that cooperation will evolve in a structured population as long as the benefit to cost ratio b/c is higher than the number of neighbours. In **Perc2011**, graphs were a probability of rewiring ones connections was considered were studied. The rewire could be with any given node in the graphs and not just with immediate neighbours. Perc et al. concluded that "making new friends" may be an important activity for the successful evolution of cooperation, but also they must be selected carefully and one should keep their number limited.
Figure 2.2: Spatial neighbourhoods

Another approach for increasing the likelihood of cooperation by increasing of assortative interactions among cooperative agents, include partner identification methods such as reputation **Janssen2006**; **Nowak1998**; **Suzuki2005**, communication tokens **Miller2002** and tags **Choi2006**; **Hales2000**; **Miller2002**; **Riolo2001**.

In this section evolutionary dynamics and the emergence of cooperation were reviewed. The following section focuses on strategy archetypes, training methods and strategies obtained from training.

2.5 Structured strategies and training

This section covers strategies that are different to that of intelligent design discussed in Section 2.3. These are strategies that have been **trained** using generic strategy archetypes. For example, in **Axelrod1987** Axelrod decided to explore deterministic strategies that took into account the last 3 turns of the game. As discussed in Section 2.3.1, for each turn there are 4 possible outcomes, CC, CD, DC, DD, thus for 3 turns there are a total of $4 \times 4 \times 4 = 64$ possible combinations. Therefore, the strategy can be defined by a series of 64 C's/D's, corresponding to each combination; this type of strategy is called a lookup table. This lookup table was then trained using a genetic algorithm **Koza1997**. During the training process random changes are made to a given lookup table. If the utility of the strategy has increased this change is kept,

otherwise not.

In 1996 John Miller considered finite state automata as an archetype **Miller1996**, more specifically, Moore machines **moore1956**. He used a genetic algorithm to train finite state machines in environments with noise. Miller's results showed that even a small difference in noise (from 1% to 3%) significantly changed the characteristics of the evolving strategies. The strategies he introduced were **Punish Twice**, **Punish Once for Two Tats** and **Punish Twice and Wait**. In **Ashlock2006b** finite state automata and genetic algorithms were also used to introduce new strategies. In a series of experiments where the size of the population varied, there were two strategies frequently developed by the training process and more over they were developed only after the evolution had gone on for many generations. These were **Fortess3** and **Fortess4**. Following Miller's work in 1996, the first structured strategies based on neural networks that had be trained using a genetic algorithm was introduced in **Harrald1996** by Harrald and Fogel. Harrald and Fogel considered a single layered neural network which had 6 inputs. These were the last 3 moves of the player and the opponent, similar to **Axelrod1987**. Neural networks have broadly been used to train IPD strategies since then with genetic algorithms **Ashlock2006a**; **Chong2005**; **Marks1999** and particle swarm optimization **Franken2005**.

In **Knight2017**; **KnightHGC17** both genetic algorithm and particle swarm optimization were used to introduce a series of structured strategies based on lookup tables, finite state machines, neural networks, hidden Markov models **eddy1996** and Gambler. Hidden Markov models, are a stochastic variant of a finite state machine and Gamblers are stochastic variants of lookup tables. The structured strategies that arised from the training were put up against a large number of strategies in (1) a Moran process, which is an evolutionary model of invasion and resistance across time during which high performing individuals are more likely to be replicated and (2) a round robin tournament. In a round robin tournament which was simulated using the software **axelrodproject** and the 200 strategies implemented within the software, the top spots were dominated by the trained strategies of all the archetypes. The top three strategies were **Evolved LookUp 2 2 2**, **Evolved HMM 5** and **Evolved FSM 16**.

In **KnightHGC17** it was demonstrated that these trained strategies would overtake the population in a Moran process. The strategies evolved an ability to recognise themselves by using a handshake. This recognition mechanism allowed the strategies to resist invasion by increasing the interactions between themselves, an approach similar to the one described in Section 2.4.

Throughout the different methods of training that have been discussed in this section, a spectrum of structured strategies can be found. Differentiating between strategies is not always straightforward. It is not obvious looking at a finite state diagram how a

machine will behave, and many different machines, or neural networks can represent the same strategy. For example Figure 2.3 shows two finite automata and both are a representation of Tit for Tat.

(a) Tit for Tat as a finite state machine with 1 state.

(b) Tit for Tat as a finite state machine with 2 states.

Figure 2.3: Finite state machine representations of Tit for Tat. A machine consists of transition arrows associated with the states. Each arrow is labelled with A/R where A is the opponent's last action and R is the player's response. Finite state machines consist of a set of internal states. In (a) Tit for Tat finite state machine consists of 1 state and in (b) of 2.

To allow for identification of similar strategies a method called fingerprinting was introduced in **Ashlock2005**. The method of fingerprinting is a technique for generating a functional signature for a strategy **Ashlock2008**. This is achieved by computing the score of a strategy against a spectrum of opponents. The basic method is to play the strategy against a probe strategy with varying noise parameters. In **Ashlock2005** Tit for Tat is used as the probe strategy. In Figure 2.4 an example of Pavlov's fingerprint is given. Fingerprinting has been studied in depth in **Ashlock2008**; **Ashlock2009**; **Ashlock2010**; **Ashlock2006a**. Another type of fingerprinting is the transitive fingerprint **axelrodproject**. The method represents the cooperation rate of a strategy against a set of opponents over a number of turns. An example of a transitive fingerprint is given in Figure 2.5.

This section covered structured strategies and training methods. In the following section software that has been developed with main aim simulating the IPD is presented.

2.6 Software

The research of the IPD heavily relies on software. This is to be expected as computer tournaments have become the main means of simulating the interactions in an IPD game. Many academic fields suffer from lack of source code availability and the IPD is not an exception. Several of the tournaments that have been discussed so far were generated using computer code, though not all of the source code is available. The code for Axelrod's original tournament is known to be lost and moreover for the second
Figure 2.4: Pavlov fingerprinting with Tit for Tat used as the probe strategy. Figure
was generated using **axelrodproject**.
Figure 2.5: Transitive fingerprint of Tit for Tat against a set of 50 random opponents.

tournament the only source code available is the code for the 62 strategies (found on
Axelrod's personal website **fortan˙code**).

Several projects, however, are open, available and have been used as research tools or
educational platforms over the years. Two research tools **prison**; **axelrodproject** and
two educational tools **pd˙trust**; **pd˙game** are briefly mentioned here. Both **prison**;
axelrodproject are open source projects. The "Game of Trust" **pd˙trust** is an on-
line, graphical user interface educational platform for learning the basics of game theory,
the IPD and the notion of strategies. It attracted a lot of attention due to being "well-
presented with scribble-y hand drawn characters" **trust˙blogb** and "a whole heap of
fun" **trust˙bloga**. Finally **pd˙game** is a personal project written in PHP. It is a
graphical user interface that offers a big collection of strategies and allows the user to
try several matches and tournament configurations.

PRISON **prison** is written in the programming language Java and a preliminary ver-
sion was launched on 1998. It was used by its authors in several publications, such
as **Beaufils1997**, which introduced Gradual, and **Beaufils1988**. The project includes
a good number of strategies from the literature but unfortunately the last update of
the project dates back to 2004. Axelrod-Python **axelrodproject** is a software used
by **Knight2017**; **KnightHGC17**; **Goodman2018**; **Wang2017**. It is written in the
programming language Python following best practice approaches **Aberdour2007**;
Benureau2018 and contains the largest collection of strategies, known to the author.
The strategy list of the project has been cited by publications **Anastassacos2018**;
Hayes2017; **Neumann2018**.

2.7 Conclusion

This manuscript presented a literature review on the Iterated Prisoner's Dilemma.
The opening sections focused on research trends and published works of the field,
followed by a presentation of research and educational software. More specifically,
Section 2.2 covered the early years of research. This was when simulating turns of
the game was only possible with human subject research. Following the early years,
the pioneering tournaments of Axelord were introduced in Section 2.3. Axelrod's work
offered the field an agent based game theoretic framework to study the IPD. In his
original papers he asked researchers to design strategies to test their performance with
the new framework. The winning strategy of both his tournaments was Tit for Tat.
The strategy however came with limitations which were explored by other researchers,
and new intelligently designed strategies were introduced in order to surpass Tit for
Tat with some contributions such as Pavlov and Gradual.

Soon researchers came to realise that strategies should not just do well in a tournament
setting but should also be evolutionary robust. Evolutionary dynamic methods were

applied to many works in the field, and factors under which cooperation emerges were explored, as described in Section 2.4. This was not done only for unstructured populations, where all strategies in the population can interact with each other, but also in population where interactions were limited to only strategies that were close to each other. In such topologies it was proven that even in the one shot game, cooperation can indeed emerge.

Evolutionary approaches can offer many insights in the study of the PD. In evolutionary settings strategies can learn to adapt and take over population by adjusting their actions; such algorithms can be applied so that evolutionarily robust strategies can emerge. Algorithms and structures used to train strategies in the literature were covered in Section 2.5. From these training methods several strategies are found, and to be able to differentiate between them fingerprinting was introduced. The research of best play and cooperation has been going on since the 1950s, and for simulating the game software has been developed along the way. This software has been briefly discussed in Section 2.6.

The study of the PD is still an ongoing field research where new variants and new structures of strategies are continuously being explored **Ohtsuki2018**. The game now serves as a model in a wide range of applications, for example in medicine and the study of cancer cells **archetti2018**; **Kaznatchee2017**, as well as in social situations and how they can be driven by rewards **Dridi2018**. New research is still ongoing for example in evolutionarily dynamics on graphs **Allen2017**; **hathcock2018**; **Liu2017**.

Chapter 3

A bibliometric study of research topics, collaboration and influence in the field of the Iterated Prisoner's Dilemma

This manuscript explores the research topics and collaborative behaviour of authors in the field of the Prisoner's Dilemma using topic modeling and a graph theoretic analysis of the co-authorship network. The analysis identified five research topics in the Prisoner's Dilemma which have been relevant of the course of time. These are human subject research, biological studies, strategies, evolutionary dynamics on networks and modeling problems as a Prisoner's Dilemma game. Moreover, the results demonstrated the Prisoner's Dilemma is a field of continued interest, and although it is a collaborative field, it is not necessarily more collaborative than other scientific fields. The co-authorship network suggests that authors are focused on their communities and not many connections across the communities are made. The Prisoner Dilemma authors also do not influence or gain much information by their connections, unless they are connected to a "main" group of authors.

3.1   Introduction

The Prisoner's Dilemma (PD) is a well known game used since its introduction in the 1950's **Flood1958** as a framework for studying the emergence of cooperation; a topic of continued interest for mathematical, social **Perc2008**, biological **Turner1999** and ecological **Wu2011** sciences. This manuscript presents a bibliometric analysis of 2,420 published articles on the Prisoner's Dilemma between 1951 and 2018. It presents the dominant topics in the PD publications, which have been identified using Latent

Dirichlet Allocation **Blei2003**, and it explores the changes in the dominant topics over time. The collaborative behaviour of the field is explored using the co-authorship network, and furthermore, the Latent Dirichlet Allocation topic analysis is combined with the co-authorship network analysis to assess the relative influence of authors in these topics. Assessing the collaborative behaviour of the field of collaboration itself is the main aim of this work.

As discussed in **youngblood2018**, bibliometrics (the statistical analysis of published works originally described by **pritchard1969**) has been used to support historical assumptions about the development of fields **raina1998**, identify connections between scientific growth and policy changes **das2016**, develop a quantitative understanding of author order **sekara2018**, and investigate the collaborative structure of an interdisciplinary field **Liu2015**. Most academic research is undertaken in the form of collaborative effort and as **Kyvik2017** points out, it is rational that two or more people have the potential to do better as a group than individually. Indeed this is the very premise of the Prisoner's Dilemma itself. Collaboration in groups has a long tradition in experimental sciences and it has be proven to be productive according to **Etzkowitz1992**. The number of collaborations can be different between research fields and understanding how collaborative a field is not always an easy task. Several studies tend to consider academic citations as a measure for these things. A blog post published by Nature **nature˙blog** argues that depending on citations can often be misleading because the true number of citations can not be known. Citations can be missed due to data entry errors, academics are influenced by many more papers than they actually cite and several of the citations are superficial.

A more recent approach to measuring collaborative behaviour, and to studying the development of a field is to use the co-authorship network, as described in **Liu2015**. The co-authorship network has many advantages as several graph theoretic measures can be used as proxies to explain author relationships. For example the average degree of a node corresponds to the average number of an authors' collaborators, and clustering coefficient corresponds to the extent that two collaborators of an author also collaborate with each other. In **Liu2015**, the approach was applied to analyse the development of the field "evolution of cooperation", and in **youngblood2018** to identify the subdisciplines of the interdisciplinary field of "cultural evolution" and investigate trends in collaboration and productivity between these subdisciplines. Moreover, **Li2019** examined the long-term impact of co-authorship with established, highly-cited scientists on the careers of junior researchers. This paper builds upon the work done by **Liu2015** and **youngblood2018**, and extends their methodology. In **Liu2015**; **youngblood2018**, a data set from a single source, Web of Science, is considered whereas the data set described here, archived at **pd˙data˙2018**, has been collected from five sources.

Latent Dirichlet Allocation (LDA) is a topic modeling technique proposed in **Blei2003** as a generative probabilistic model for discovering underlying topics in collections of data. Applications of the technique include detection in image data **Agarwal2008**; **Coelho2010** and detection in video **Niebles2008**; **Wang2008**. Nevertheless, LDA has been applied by several works on publication data for identifying the topic structure of a subject area. In **Inglis2018**, it was applied to the publications on mathematical education of the journals "Educational Studies in Mathematics" and "Journal for Research in Mathematics Education" to identify the dominant topics that each journal was publishing on. The topics of the North American library and Information Science dissertations were studied chronologically in **Sugimoto2011**, and the main topic of the scientific content presented at EvoLang conferences was identified in **Bergmann2018**. In **Bergmann2018** the LDA approach is combined with clustering and a co-authorship network analysis. A clustering analysis is applied to the LDA topics, and the co-authorship network is analysed as a whole where the clusters are only used to differentiate between the authors' topics. In comparison, this works applies LDA to identify dominant topics in the Prisoner's Dilemma fields and analyses the networks corresponding to these topics individually.

The methodology used in this manuscript (including the data collection) is covered in Section 3.2 and a preliminary analysis of the data set is presented in Section 3.3. This manuscript makes usage of the methodology and data to address the following questions:

1. What are the research topics of the Prisoner's Dilemma?

2. Is one topic currently more in fashion?

3. How have the research topics changed over the years?

4. Is the Prisoner's Dilemma a collaborative field?

5. Are some topics more collaborative than others?

6. Are there authors which benefit more from their position in the network?

Results regarding questions 1-3 are presented in Section 3.4 and questions 4-6 are addressed in Section 3.5. The results are summarised in Section 3.6.

3.2 Methodology

Academic articles are accessible through scholarly databases. Several databases and collections today offer access through an open application protocol interface (API). An API allows users to query directly a journal's database and bypass the graphical user interface. Interacting with an API has two phases: requesting and receiving. The request phase includes composing a url with the details of the request.

For example, `http://export.arxiv.org/api/query?search_query=abs:prisoner'` `sdilemma&max_results=1` represents a request message. The first part of the request is the address of the API. In this example the address corresponds to the API of arXiv. The second part of the request contains the search arguments. In this example it is requested that the word 'prisoners dilemma' exists within the article's title. The format of the request message is different from API to API. The receive phase includes receiving a number of raw metadata of articles that satisfies the request message. The raw metadata are commonly received in extensive markup language (xml) or Javascript object notation (json) formats **nurseitov2009**. Similarly to the request message, the structure of the received data differs from journal to journal.

The data collection is crucial to this study. To ensure that this study can be reproduced all code used to query the different APIs has been packaged as a Python library and is available online **nikoleta˙2017**. The software could be used for any type of projects similar to the one described here, documentation for it is available at: `http://arcas.` `readthedocs.io/en/latest/`. Project **nikoleta˙2017** allow users to collect articles from a list of APIs by specifying just a single keyword. Articles for which any of the terms "prisoner's dilemma", "prisoners dilemma", "prisoner dilemma", "prisoners evolution", "prisoner game theory" existed within the title, the abstract or the text are included in the analysis. Four prominent journals in the field and a preprint server were used as sources to collect data for this analysis:

- arXiv **mckiernan2000**; a repository of electronic preprints. It consists of scientific papers in the fields of mathematics, physics, astronomy, electrical engineering, computer science, quantitative biology, statistics, and quantitative finance, which all can be accessed online.

- PLOS **plos**; a library of open access journals and other scientific literature under an open content license. It launched its first journal, PLOS Biology, in October 2003 and publishes seven journals, as of October 2015.

- IEEE Xplore Digital Library (IEEE) **ieee**; a research database for discovery and access to journal articles, conference proceedings, technical standards, and related materials on computer science, electrical engineering and electronics, and allied fields. It contains material published mainly by the Institute of Electrical and Electronics Engineers and other partner publishers.

- Nature **nature**; a multidisciplinary scientific journal, first published on 4 November 1869. It was ranked the world's most cited scientific journal by the Science Edition of the 2010 Journal Citation Reports and is ascribed an impact factor of 40.137, making it one of the world's top academic journals.

- Springer **springer**; a leading global

scientific publisher of books and   academic and professional society
journals. It publishes close to 500   journals.

The data set has been archived and is available at **pd˙data˙2018**. Note that the latest data collection was performed on the 30$^{\text{th}}$ November 2018.

The relationship between the authors within a field will be modeled as a graph $G = (V_G, E_G)$ where V_G is the set of nodes and E_G is the set of edges. The set V_G represents the authors and an edge connects two authors if and only if those authors have written together. This co-authorship network is constructed using the main data set **pd˙data˙2018** and the open source package **networkx**. The PD network is denoted as G where the number of unique authors $|V(G)|$ is 4226 and $|E(G)|$ is 7642 . All authors' names were formatted as their first name and last name (i.e. Martin A. Nowak to Martin Nowak). This was done to avoid errors such as Martin A. Nowak and Martin Nowak being treated as a different person. There are some authors for which only their first initial was found. These entries are left as such.

The collaborativeness of the authors will be analysed using measures such as, isolated nodes, connected components, clustering coefficient, communities, modularity and average degree. These measures show the number of connections authors can have and how strongly connected these people are. The number of isolated nodes is the number of nodes that are not connected to another node, thus the number of authors that have published alone. The average degree denotes the average number of neighbours for each nodes, i.e. the average number of collaborations between the authors. A connected component is a maximal set of nodes such that each pair of nodes is connected by a path **Easley2010**. The number of connected components as well as the size of the largest connected component in the network are reported. The size of the largest connected component represents the scale of the central cluster of the entire network, as will be discussed in the analysis section. Clustering coefficient and modularity are also calculated. The clustering coefficient, defined as 3 times the number of triangles on the graph divided by the number of connected triples of nodes, is a local measure of the degree to which nodes in a graph tend to cluster together in a clique **Easley2010**. It shows to which extent the collaborators of an author also write together. In comparison, modularity is a global measure designed to measure the strength of division of a network into communities. The number of communities will be reported using the Clauset-Newman-Moore method **clauset2004**. Also the modularity index is calculated using the Louvain method described in **Blondel2008**. The value of the modularity index can vary between $[-1, 1]$, a high value of modularity corresponds to a structure where there are dense connections between the nodes within communities but sparse connections between nodes in different communities. That means that there are many sub communities of authors that write together but

not across communities. Two further points are aimed to be explored in this work, (1) which people control the flow of information; as in which people influence the field the most and (2) which are the authors that gain the most from the influence of the field. To measure these concepts centrality measures are going to be used. Centrality measures are often used to understand different aspects of social networks **Landherr2010**. Two centrality measures have been chosen for this paper and these are closeness and betweenness centrality.

1. In networks some nodes have a short distance to a lot of nodes and consequently are able to spread information on the network very effectively. A representative of this idea is **closeness centrality**, where a node is seen as centrally involved in the network if it requires only few intermediaries to contact others and thus is structurally relatively independent. Closeness centrality is interpreted as influence. Authors with a high value of closeness centrality, are the authors that spread scientific knowledge easier on the network and they have high influence.

2. Another centrality measure is the **betweenness centrality**, where the determination of an author's centrality is based on the quotient of the number of all shortest paths between nodes in the network that include the node in question and the number of all shortest paths in the network. In betweenness centrality the position of the node matters. Nodes with a higher value of betweenness centrality are located in positions that a lot of information pass through, this is interpreted as the gain from the influence, thus these authors gain the most from their networks.

The articles contained in the data set (**pd˙data˙2018**) will be classified into research topics using LDA an unsupervised machine learning technique designed to summarize large collections of documents by a small number of conceptually connected topics or themes **Blei2003**; **Grimmer2013**. The documents are the articles' abstracts and LDA was carried out using **rehurek˙lrec**. In LDA, each document/abstract is represented by a distribution over topics, and the topics themselves are represented by a distribution over words. More specifically, each topics is described by weights associated with words and each document by the probabilities of belonging to a specific topic. The probability of a document belonging to a topic is referred to as the percentage contribution denoted as c. For example the words and their associated weights for two topics A and B could be:

- Topic A: $0.039\times$ "cooperation", $0.028\times$ "study" and $0.026\times$ "human".

- Topic B: $0.020\times$ "cooperation", $0.028\times$ "agents" and $0.026\times$ "strategies".

The percentage contribution for a document with abstract "The study of cooperation in humans" has a $c_A = 0.039+0.028+0.026 = 0.093$ and $c_B = .020+0.0+0.0 = 0.020$. The

topic to which a document is assigned to is based on the highest percentage contribution denoted as c^*. For the given example the dominant topic is Topic A $c^* = c_A$. LAD requires that the number of topics is specified in advance before running the algorithm. The number of topics can be chosen using the coherence value **Roder2015** or through subjective minimisation of the overlapping keywords between two topics. Both these approaches will be used in this work.

Several of the approaches described in this section have previously been carried out in **Bergmann2018**; **Liu2015**; **Sugimoto2011**; **youngblood2018**, the novelty here is combining the approaches as well as applying them to a new data set. A preliminary analysis of the data set is presented in the following section.

3.3   Preliminary Analysis

The data set **pd˙data˙2018** consists of 2422 articles with unique titles. In case of duplicates the preprint version of an article (collected from arXiv) was dropped. Similarly to **Liu2015**, 76 articles have not been collected from the aforementioned APIs but have been manually added because they are of interest. Examples of such papers include **Flood1958** the first publication on the PD, **Ohtsuki2006**; **Stewart2012** two well cited articles in the field, and a series of works from Robert Axelrod **Axelrod1980**; **Axelrod1980more**; **Axelrod1987**; **Axelrod1981**; **Riolo2001** a leading author of the field. A more detailed summary of the articles' provenance is given by Table 3.1. Only 3% of the data set consists of articles that were manually added and 27% of the articles were collected from arXiv. The average number of publications is also included in Table 3.1. Overall an average of 43 articles are published per year on the topic. The most significant contribution to this appears to be from arXiv with 11 articles per year, followed by Springer with 9 and PLOS with 8.

	Number of Articles	Percentage %	Year of first publication	Average number of publications per year
IEEE	294	12.14%	1973	5
Manual	76	3.14%	1951	1
Nature	436	18.00%	1959	8
PLOS	477	19.69%	2005	8
Springer	533	22.01%	1966	9
arXiv	654	27.00%	1993	11
Overall	2470	100.00%	1951	43

Table 3.1: Summary of **pd˙data˙2018** per provenance.

The data handled here is in fact a time series from the 1950s, the formulation of the game, until 2018 (Figure 3.1). Two observations can be made from Figure 3.1.

1. There is a steady increase of the number of publications since the 1980s and the introduction of computer tournaments **Axelrod1981** (work by Robert Axelrod).

2. There is a decrease in 2017-2018. This is due to our data set being incomplete. Articles that have been written in 2017-2018 have either not being published or were not retrievable by the APIs at the time of the last data collection.

These observations can be confirmed by studying the time series. Using **scipy**, an exponential distribution is fitted to the data. The fitted model can be used to forecast the behaviour of the field for the next 5 years. Even though the time series has indicated a slight decrease, the model forecasts that the number of publications will keep increasing, thus demonstrating that the field of the PD continues to attract academic attention.
Figure 3.1: Number of articles published on the PD 1951-2018 (on a log scale), with a fitted exponential line, and a forecast for 2017-2022.

There are a total of 4226 authors in the data set (**pd˙data˙2018**) and several of these authors have had multiple publications collected from the data collection process. The highest number of articles collected for an author is 83 publications for Matjaz Perc. The distribution of the number of papers per author is given by Figure 3.2, and it can be seen that Matjaz Perc is an outlier. More specifically, most authors have 1 to 6 publications in the data set.
Figure 3.2: Distribution of number of papers per author (on a log scale).

The overall Collaboration Index (CI) or the average number of authors on multi-

authored papers is 3.2, thus on average a non single author publication in the PD has 3 authors. This appears to be quite standard compared to other fields such as cultural evolution **youngblood2018**, Astronomy and Astrophysics, Genetics and Heredity, Nuclear and Particle Physics as reported by **nature˙author˙blog**. There are only a total of 545 publications with a single author, which corresponds to the 22% of the papers. It appears that academic publications tend to be undertaken in the form of collaborative effort, which is in line with the claim of **Kyvik2017**. From Figure 3.3 the trend of CI over the years is given. There are some peaks in the early years 1969 and 1980, however, a steady increase appears to happen after 2004. This could be an effect of better communication tools being introduced around that time which enabled more collaborations between researchers.
Figure 3.3: Collaboration index over time.

The collaborativeness of the authors is explored in more detail in Section 3.5 using the co-authorship network. The collaborative behaviour and relative influence of authors will also be explored in co-authorship networks which correspond to their publications research topics. These topics are presented in the next section.

3.4 Research topics in the Prisoner's Dilemma research

In order to identify the topics which are being discussed in the field of the PD, the LDA algorithm implemented in **rehurek˙lrec** is applied to the abstracts of the data set. As mentioned before, the number of topics, which will be denoted as n, needs to be specified before running the algorithm. The appropriate number of topics is chosen based on the coherence value **Roder2015**. Figure 3.4 gives the coherence values of 18 models where $n \in \{2, 3, \ldots, 19\}$, and it can be seen than the most appropriate number of topics is 6 with a coherence value of 0.418.

An LDA model outputs an $N \times n$ matrix - N rows for N abstracts and n columns for n topics. The cells contain the percentage contributions for each topic for each abstract, c_i^j for $i \in \{1, 2, \ldots, n\}$ for $j \in \{1, 2, \ldots, N\}$. In essence, LDA maps every paper to a
Figure 3.4: Coherence for LDA models over the number of topics.

vector space of dimension the number of topics. In the case of 6 topics it is difficult to visualise the clustering of topics. To overcome this a dimensionality reduction approach called t-Distributed Stochastic Neighbor Embedding (t-SNE) **Maaten2008** is applied to the LDA model outputs. More specifically, t-SNE is used to reduce the dimensions of each c^j from n to 2. Figure 3.5, gives the visualisation of LDA for $n = 6$. Each point represents a single document and its color corresponds to the topic with the highest percentage contribution. The documents which are clustered together have a similar percentage contribution distribution over the topics.

Even though the LDA model with $n = 6$ has the highest coherence value, Figure 3.5 shows that documents of the same topic are closer to documents from other topics than each other. For example the documents of topic 2 are divided into two clusters. The one cluster is closer to documents from topic 4 and the other has a few documents closer to topic 1. In the case of $n = 6$ topic 4 appears to be on "evolution of cooperation on networks", and the papers from topic 2 surrounded from topic 4 include the articles "Evolutionary prisoner's dilemma game on hierarchical lattices" **Vukov2005** and "Social evolution in structured populations" **Debarre2014**. Publications that clearly also fit topic 4.

In comparison, 3.6 gives the visualisation of LDA $n = 5$ where the separation of the documents is more clear. Though several models, Figure 3.4, have a higher coherence value than the LDA model with $n = 5$, the separation of topics is not as clear for any model as it is for $n = 5$. Thus, $n = 5$ is chosen to carry out the analysis of this work, and moreover the LDA model for $n = 5$ has a coherence value 0.406 which is close to 0.418.

What are the research topics of the Prisoner's Dilemma?

For $n = 5$ the articles are clustered and assigned to their dominant topic, based on the highest percentage contribution. The keywords associated with a topic, the most representative article of the topic (based on the percentage contribution) and its academic reference are given by Table 3.2. The topics are labelled as A, B, C, D and E,
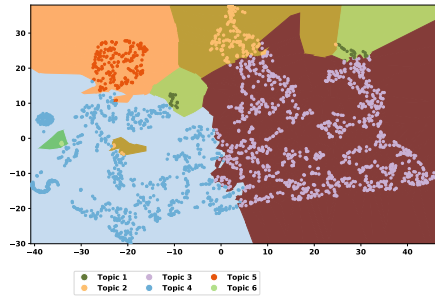

Figure 3.5: Visualisation of LDA with $n = 6$ on 2 dimensions.
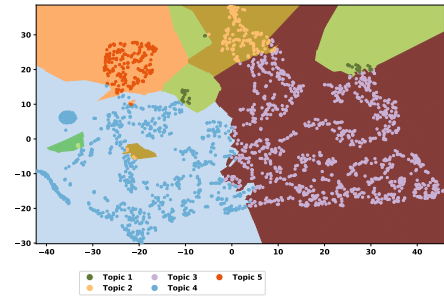

Figure 3.6: Visualisation of LDA with $n = 5$ on 2 dimensions.

and more specifically:

- Based on the keywords associated with Topic A, and the most representative article, Topic A appears to be about **human subject research**. Several publications assigned to the topic study the PD by setting experiments and having human participants simulate the game instead of computer simulations. These articles include **Matsumoto2016** which showed that prosocial behavior increased with the age of the participants, **Li2014** which studied the difference in cooperation between high-functioning autistic and typically developing children, **Molina2013** explored the gender effect in highschool students and **Bell2017** explored the effect of facial expressions of individuals.

- Though it is not immediate from the keywords associated with Topic B, investigating the papers assigned to the topic indicate that it is focused on **biological studies**. Papers assigned to the topic include papers which apply the PD to genetics **Santorelli2008**; **Sistrom2015**, to the study of tumours **archetti2013evolutionary**; **sartakhti2017** and viruses **turner1999prisoner**. Other works include how phenotype affinity can affect the emergence of cooperation **wu2019phenotype** and modeling bacterial communities as a spatial structured social dilemma.

- Based on the keywords and the most representative article Topic C appears to include publications on PD **strategies**. Publications in the topic include the introduction of new strategies **stewart2013extortion**, the search of optimality in strategies **banerjee2007reaching** and the training of strategies **ishibuchi2011evolution** with different representation methods. Moreover, publications that study the evolutionary stability of strategies **adami2013evolutionary** and introduced methods of differentiating between them **ashlock2008fingerprinting** are also assigned to C.

- The keywords associated with Topic D clearly show that the topic is focused on **evolutionary dynamics on networks**. Publications include **ichinose2013robustness** which explored the robustness of cooperation on networks, **wang2012spatial**

which studied the effect of a strategy's neighbourhood on the emergence of cooperation and **chen2016fixation** which explored the fixation probabilities of any two strategies is spatial structures.

- The publication assigned to Topic E are on **modeling problems as a PD game**. Though Topic B is also concerned with problems being formulated as a PD, it includes only biological problems. In comparison, the problems in Topic E include decision making in operational research **ormerod2010or**, information sharing among members in a virtual team **feng2008trilateral**, the measurement of influence in articles based on citations **hutchins2016relative** and the price spikes in electric power markets **Guan2002**, and not on biological studies.

Dominant Topic	Topic Keywords	Most Representative Article Title	Reference	# Documents	% Documents
A	social, behavior, human, study, experiment, cooperative, cooperation, suggest, find, behaviour	Facing Aggression: Cues Differ for Female versus Male Faces	**Geniole2012**	496.0	0.2008
B	individual, group, good, show, high, increase, punishment, cost, result, benefit	Genomic and Gene-Expression Comparisons among Phage-Resistant Type-IV Pilus Mutants of Pseudomonas syringae pathovar phaseolicola	**Sistrom2015**	309.0	0.1251
C	game, strategy, player, agent, dilemma, play, payoff, state, prisoner, equilibrium	Fingerprinting: Visualization and Automatic Analysis of Prisoner's Dilemma Strategies	**Sistrom2015**	561.0	0.2271
D	cooperation, network, population, evolutionary, evolution, interaction, dynamic, structure, cooperator, study	Influence of initial distributions on robust cooperation in evolutionary Prisoner's Dilemma	**Chen2007**	556.0	0.2251
E	model, theory, base, system, problem, paper, propose, information, provide, approach	Gaming and price spikes in electric power markets and possible remedies	**Guan2002**	548.0	0.2219

Table 3.2: Keywords for each topic and the document with the most representative article for each topic.

Note that the whilst for the choice of 5 topics the actual clustering is not subjective (the algorithm is determining the output) the interpretation above is.

Five topics in the PD publications identified by the data set of this work are human subject research, biological studies, strategies, evolutionary dynamics on networks and modeling problems as a PD.

These 5 topics nicely summarise the PD research. They highlight the interdisciplinarity of the field; how it brings together applied modeling of real world situations (Topic B and E) and more theoretical notions such as evolutionary dynamics and optimality of

strategies.

Is one topic currently more in fashion?

Figure 3.7 gives the number of articles per topic over time. The topics appear to have had a similar trend over the years, with topics B and D having a later start. Following the introduction of a topic the publications in that topic have been increasing. There is no decreasing trend in any of the topics. All the topics have been publishing for years and they still attract the interest of academics. Thus, **there does not seem to be any given topic more or less in fashion**.
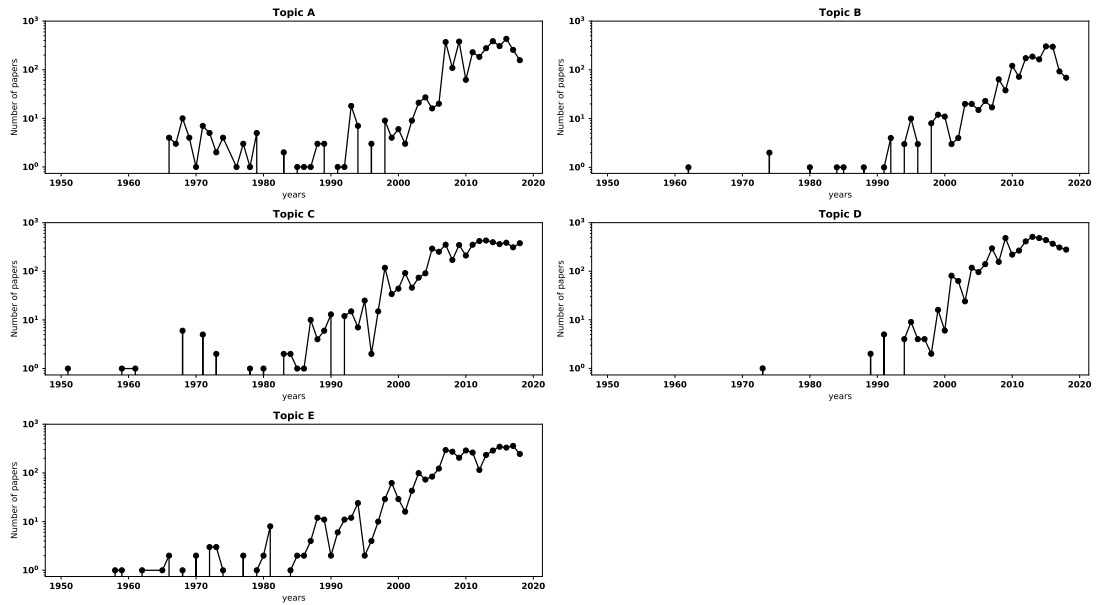

Figure 3.7: Number of articles per topic over the years (on a logged scale).

How do the research topics change over the years?

To gain a better understanding regarding the change in the topics over the years, LDA is applied to the cumulative data set over 8 time periods. These periods are 1951-1965, 1951-1973, 1951-1980, 1951-1988, 1951-1995, 1951-2003, 1951-2010, 1951-2018. The number of topics for each cumulative subset is chosen based on the coherence value and no objective approach is used. As a result, the period 1951-2018 has been assigned $n = 6$ which had the highest coherence value instead of 5. The chosen models for each period including the number of topics, their keywords and number of articles assigned to them are given by Table 3.3.

But how well do the five topics which were presented earlier fit the publications over time? This is answered by comparing the performance of three LDA models over the cumulative periods' publications. The three models are LDA models for the entire data set for n equal to 5, 6 and the optimal number of topics over time. For each model the c^* is estimated for each document in the cumulative data sets. The performance of the

Period	Topic	Topic Keywords	Num of Documents	Percentage of Documents

Table 3.3: Topic modeling result for the cumulative data set over the periods

models are then compared based on:

$$\bar{c^*} \times n \tag{3.1}$$

where $\bar{c^*}$ is the median highest percentage contribution and n is the number of top-
ics of a given period. A model with more topics will have more difficulty to assign
papers. Thus, equation (refeq:ratio) is a measure of confidence in assigning a given
paper to its topic weighted by the number of topics. The performances are given by
Figure 3.8.

The five topics of the PD presented in this manuscript appear to always be less good
at fitting the publications compared to the six topics of LDA $n = 6$. Moreover, there
are less good than the topics of the optimal number of topics from 1951 to 1995.
The difference in the performance values, equation (3.1), however are small. **The
relevances of the five topics has been increasing over time, and though, the
topics did not always fit the majority of published work over time, there
were still papers being published on those topics**.

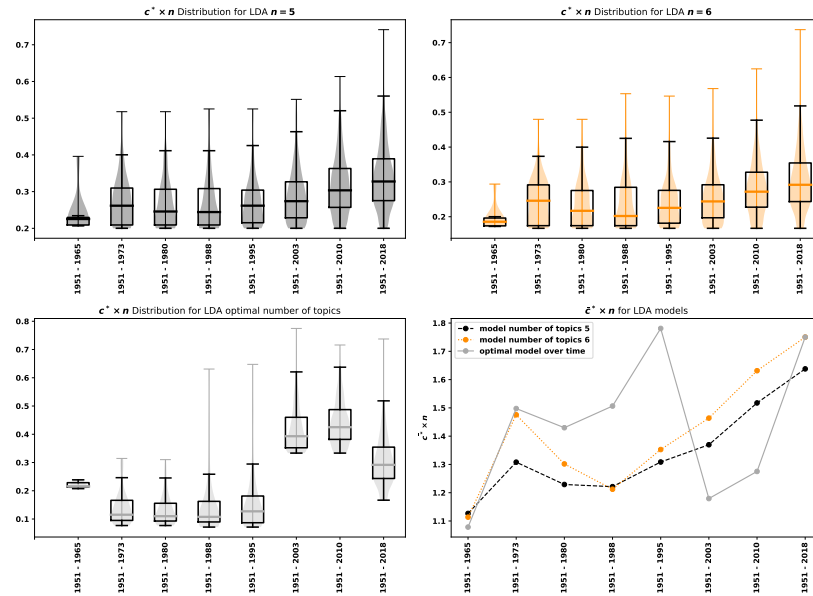

Figure 3.8: Maximum percentage contributions (c^*) over the time periods, for the LDA
models for the entire data set for n equal to 5, 6 and the optimal number of topics over
time.

In the following section the collaborative behaviour of authors in the field, and within
the field's topics as were presented in this section, are explored using a network theoretic
approach.

3.5   Analysis of co-authorship network

The collaborative behaviour of authors in the field of the PD is assessed using the co-authorship network, which as mentioned in Section 3.2 is denoted as G. There are a total of 947 connected components in G and the largest component has a size of 796 nodes. The largest connected component is going to be refereed to as the main cluster of the network and is denoted as $\bar{G}$. A graphical representation of both networks is shown in Figure 3.9 and a metrics summary is given by Table 3.4.

Is the Prisoner's Dilemma a collaborative field?

Based on Table 3.4 an author in G has on average 4 collaborators and a 70% probability of collaborating with a collaborator's co-author. An author of $\bar{G}$ on average is 7% more likely to write with a collaborator's co-author and on average has 2 more collaborators. Moreover, there are only 3.2 % of authors in the PD that has no connection to any other author.

How does this compare to other fields? Two more data sets for the topics "Price of Anarchy" and "Auction Games" have been collected in order to compare the collaborative behaviour of the PD to other game theoretic fields. A total of 3444 publications have been collected for Auction games and 748 for Price of Anarchy. Price of Anarchy is relatively a new field, with the first publication on the topic being **Koutsoupias1999** in 1999. This explains the small number of articles that have been retrieved. Both data sets have been archived and are available in **auction·data·2018**; **anarchy·data·2018**. The networks for both data sets have been generated in the same way as G. A summary of the networks' metrics are given by Table 3.5.

The average degrees for the Price of Anarchy and for Auction games are lower than the PD's. In Auction games an author is more likely to have no collaborators, and in the Price of Anarchy there are almost no authors that are not connected to someone. This could be an effect of the field being introduced in more modern days. Overall, an author in the PD has on average more collaborators and there are less isolated authors compared to another well established game theoretic field. These results seem to indicate that the PD is a *relatively* collaborative field.

However, both G and $\bar{G}$ have a high modularity (larger than 0.84) and a large number of communities (967 and 25 respectively). A high modularity implies that authors create their own publishing communities but not many publications from authors from different communities occur. Thus, author tends to collaborate with authors in their communities but not many efforts are made to create new connections to other communities and spread the knowledge of the field across academic teams. The fields of both Price of Anarchy and Auction games also have high modularity, and that could indicate that is in fact how academic publications are.
(a) G the co-authorship network for the IPD.
(b) $\bar{G}$ the largest connected component of G.

Figure 3.9: A graphical representation of G and $\bar{G}$

Thus, **the PD is indeed a collaborative field but perhaps it is not more
collaborative than other fields**, as there is no effort from the authors to write with
people outside their community.

	# Nodes	# Edges	% Isolated nodes	# Connected components	Size of largest component	Av. degree	# Communities	Modularity	Clustering coeff
G	4011	7642	3.2	947	796	3.811	967	0.96491	0.701
$\bar{G}$	796	2214	0.0	1	796	5.563	25	0.84406	0.773

Table 3.4: Network metrics for G and $\bar{G}$ respectively.

	# Nodes	# Edges	# Isolated nodes	% Isolated nodes	# Connected components	Size of largest component	Av. degree	# Communities	Modularity	Clustering coeff
Auction Games	5165	7861	256	5.0	1272	1348	3.044	1294	0.957	0.622
Price of Anarchy	1155	1953	4	0.3	245	222	3.382	253	0.965	0.712

Table 3.5: Network metrics for auction games and price of anarchy networks respectively.

The evolution of the networks was also explored over time by constructing the network
cumulatively over 51 periods. Except from the first period 1951-1966 the rest of the
periods have a yearly interval (data for the years 1975 and 1982 were not retrieved
by the collection data process). The metrics of each sub network are given in the
Appendix .1.

The results, similarly to the results of **Liu2015**, confirm that the networks grow over
time and that the networks always had a high modularity. Since the first publications
authors tend to write with people from their communities, and that is not an effect of
a specific time period.

Are some topics more collaborative than other?

The networks corresponding to the topics of Section 3.3 have also been generated
similarly to G. Note that authors with publications in more than one topic exist, and
these authors are included in all the corresponding networks. A metrics' summary for
all five topic networks is given by Table 3.6.

Topic B is the network with the highest average degree followed by Topic A. The topic
with the smallest average degree, 2.5, is Topic C. In topics A and B the number of
isolated nodes is very small $lessthan(0.2)$ compared to Topic E where the percentage
of isolated nodes is approximately 6%. Moreover, in topics C and E an author is 10%
more likely to collaborate with a collaborator's co-author. Thus, **topics "human
subject research" and "biological studies" tend to be more collaborative
than the topic of "strategies", and an authors in these are less likely to have
at least one collaborator compared to the topic of "modeling problems as
a PD"**.

**"Evolutionary dynamics on networks" also appear to be a collaborative
topic**. In fact the network of the topic is a sub graph of $\bar{G}$, the main cluster of

G and it will be demonstrated in the following section that authors in this network are more like to gain from the influence of the network compared to any other topic network.

	# Nodes	# Edges	# Isolated nodes	% Isolated nodes	# Connected components	Size of largest component	Av. degree	# Communities	Modularity	Clustering coeff
Topic A	1124	2137	15	1.3	264	56	3.802	265	0.983	0.759

Table 3.6: Network metrics for topic networks.

Are there authors which benefit more from their position in the network?

There are two centrality measures reported in this work, closeness and betweenness centrality. Closeness centrality is a measure of how easy it is for an author to contact others, and consequently affect them; influence them. Thus closeness centrality here is a measure of influence. Betweenness centrality is a measure of how many paths pass through a specific node, thus the amount of information this person has access to. Betweenness centrality is used here as a measure of how much an author gains from the field. All centrality measure can have values ranging from 0 to 1. The influence and the amount of information an author has access to are used to explore which authors benefit more from their position.

For G and $\bar{G}$ the most central authors based on closeness and betweenness centralities are given by Table 3.7. The most central authors in G and $\bar{G}$ are the same. This implies that the results on centrality heavily rely on the main cluster (as expected). Matjaz Perc is an author with 83 publications in the data set and the most central authors based on both centrality measures. The most central authors are fairly similar between the two measures. The author that appear to be central based on one measure and not the other are Martin Nowak, Franz Weissing, Jianye Hao, Angel Sanchez and Valerio Capraro which have access to information due to their positioning but do not influence the network as much, and the opposite is true for Attila Szolnoki, Luo-Luo Jiang Sandro Meloni, Cheng-Yi Xia and Xiaojie Chen.

It is obvious that in G the centralities values are low which suggests that in the PD authors do not benefit from their positions. This could be an effect of information not flowing from one community to another as authors tend to write with people from their communities. Nevertheless, **there are authors that do benefit from their position, but these are only the authors connected to the main cluster**.

The centrality measures for the topic networks have also been estimated and are given in Tables 3.8-3.9. If information was flowing between the communities of the research topics then there would be an increase to the values of centralities for the sub networks. However, the only topic where authors gain from their positions are the authors of Topic

Table 3.7: 10 most central authors based on betweenness and closeness centralities for G and $\bar{G}$.

D (topic on evolutionary dynamics on network). From the list of names it is obvious that these authors are part of $\bar{G}$, and that the network of Topic D is a sub network of $\bar{G}$. This confirms the results. The people benefiting from their position in the co-authorship networks corresponding to research topics of the PD are only the people from the main cluster of G.

The fact that most authors of the main cluster are primarily publishing in evolutionary dynamics on networks indicates that publishing in this specific topic differs from the other topics covered in this manuscript. There appears to be more collaboration and influence in the publications on evolutionary dynamics and authors are more likely to gain from their position, though it is not clear as to why.

The distributions of both centrality measures for all the networks of this work are given

in the Appendix .2.2.

3.6 Conclusion

This manuscript has explored the research topics in the publications of the Iterated Prisoner's Dilemma, and moreover, the authors' collaborative behaviour and their influence in the research field. This was achieved by applying network theoretic approaches and a LDA algorithm to a total of 2422 publications. Both the software **nikoleta˙2017** and the data **nikoleta˙2017** have been archived and are available to be used by other researchers. In fact **nikoleta˙2017** has been used by **brane** and **arcas˙blog**.

The data collection and an introduction to the methodology used in this work were covered in Section 3.2. Section 3.3 covered an initial analysis of the data set which demonstrated that the PD is a field that continues to attract academic attention and publications. In Section 3.4 LDA was applied to the data set to identify topics on which researchers have been publishing. The LDA analysis showed that the data could be classified into 5 topics associated with human subject research, biological studies, strategies, evolutionary dynamics on networks and modeling problems as a PD. These topics summarize the field of the PD well, as they demonstrate its interdisciplinarity and applications to a variety of problems. A temporal analysis explored how relevant these topics have been over the course of time, and it revealed that even though there were not the necessarily always the most discussed topics they were still being explored by researchers.

The collaborative behaviour of the field was explored in Section 3.5 by constructing the co authorship network. It was concluded that the field is a collaborative field, where authors are likely to write with a collaborator's co-authors and on average an author has 4 co-authors, however it not necessarily more collaborative than other fields. The authors tend to collaborate with authors from one community, but not many authors are involved in multiple communities. This however might be an effect of academic research, and it might not be true just for the field of the PD. Exploring the influence of authors and their gain from being in the network of the field demonstrated that authors do not gain much, and the authors with influence are only the ones connected to the main cluster, to a "main" group of authors. This 'main" group of authors consists of authors publishing in evolutionary dynamics on networks. Thus, an author would be aiming to publish on this topic if they were interested in gaining from their position in the publications of the PD.

The study of the PD is the study of cooperation and investigating the cooperative behaviours of authors is what this work has aimed to achieve. Interesting areas of future work would include extending this analysis to more game theoretic sub fields, to evaluate whether the results remain the same.

.2 Centrality Measures Distributions

### .2.1 Distrubutions for G and $\bar{G}$

Figure 10: Distributions of betweenness centrality in G and $\bar{G}$

### .2.2 Distrubutions for Topic Networks

Figure 11: Distributions of closeness centrality in G and $\bar{G}$

Figure 12: Distributions of betweenness centrality in topics' networks.

Figure 13: Distributions of closeness centrality in topics' networks.
